**Computer Engineering**  
Kasetsart University

# Stack ADT

# What is a Stack ADT?

- Data:
  - Elements stored in a list linearly, but are allowed insertion and deletion only **at one end**
  - This mechanism is called **LIFO** – Last in, First out
- Common operations:
  - `push(stack, value)`
  - `pop(stack)`
  - `top(stack)/peek(stack)`
  - `is_empty(stack)`
  - `is_full(stack)`
  - ...

# Stack Implementations

---

- Two types of implementation
  - Array-based stack
  - Pointer-based stack

# Stack: Array Implementation

Basic idea:

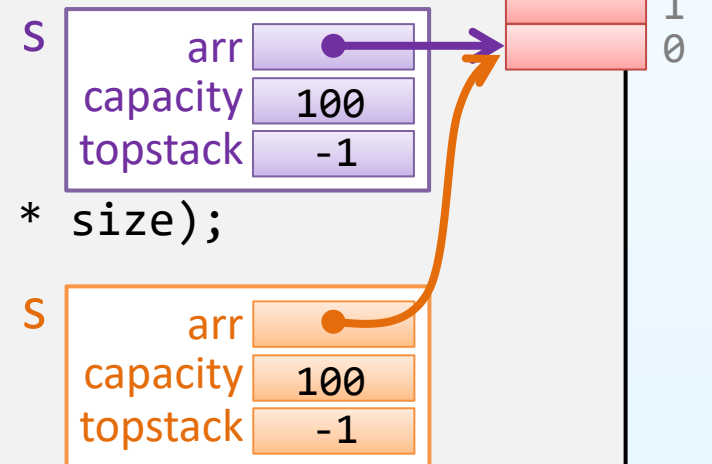

- **Allocate** a big array (of size capacity)
- **Keep track** of current size (using a variable topstack)

# Stack: Array-based Construction

Assume that all data are positive integer

```
1: #include <stdio.h>
2: #include <stdlib.h>
3:
4: typedef struct stack {
5:     int *arr;        // array-based stack
6:     int capacity;    // size of stack
7:     int topstack;    // position at the top of stack
8: } stack_t;
9:
10: stack_t create(int size) {
11:     stack_t s = {NULL, size, -1};
12:     s.arr = (int *)malloc(sizeof (int) * size);
13:     return s;
14: }
15: int main(void) {
16:     stack_t s = create(100);
17:     return 0;
18: }
```

# Array-based Stack: push() Operation

Push a value  $v$  at the top of stack  $s$

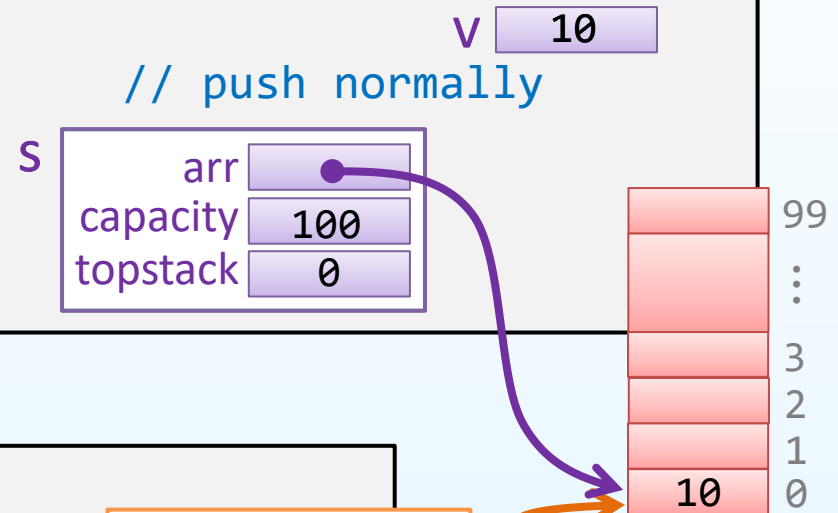

- If  $\text{topstack} < \text{capacity}$ , push  $v$  normally
- Otherwise, the stack is full

# Array-based Stack: push() Operation

Push a value  $v$  at the top of stack  $s$

```
1: int push(stack_t s, int v) {  
2:   if (s.topstack == s.capacity-1)    // stack is full  
3:     return 0;  
4:  
5:   s.topstack++;  
6:   s.arr[s.topstack] = v;  
7:  
8:   return 1;  
9: }
```

```
int main(void) {  
  stack_t s = create(100);  
  push(s, 10);  
  return 0;  
}
```

# Array-based Stack: push() Operation

Push a value  $v$  at the top of stack  $s$

```
1: int push(stack_t *s, int v) {  
2:   if (s->topstack == s->capacity-1) // stack is full  
3:     return 0;  
4:                                     v 10  
5:   s->topstack++;                     // push normally  
6:   s->arr[s->topstack] = v;  
7:                                     s  
8:   return 1;  
9: }
```

```
int main(void) {  
  stack_t s = create(100);  
  push(&s, 10);  
  return 0;  
}
```

# Exercise 1: Other Operations

---

Implement the following functions for an **array-based stack**

- `pop()` – remove the top element of stack *s*
  - Return *v* if the stack is not empty, otherwise -1
- `top()` – peek the top element of stack *s*
  - Return *v* if the stack is not empty, otherwise -1
- `is_empty()` – check whether stack *s* is empty
  - return 1 if the stack is empty, otherwise 0
- `is_full()` – check whether stack *s* is full
  - return 1 if the stack is full, otherwise 0

# Array-based Stack: Running Time

Operation	Running Time
create()	$O(1)$
push()	$O(1)$
pop()	$O(1)$
top()	$O(1)$
is_empty()	$O(1)$
make_empty()	$O(1)$
is_full()	$O(1)$
destroy()	$O(1)$

# Limitation of Array-based Stack

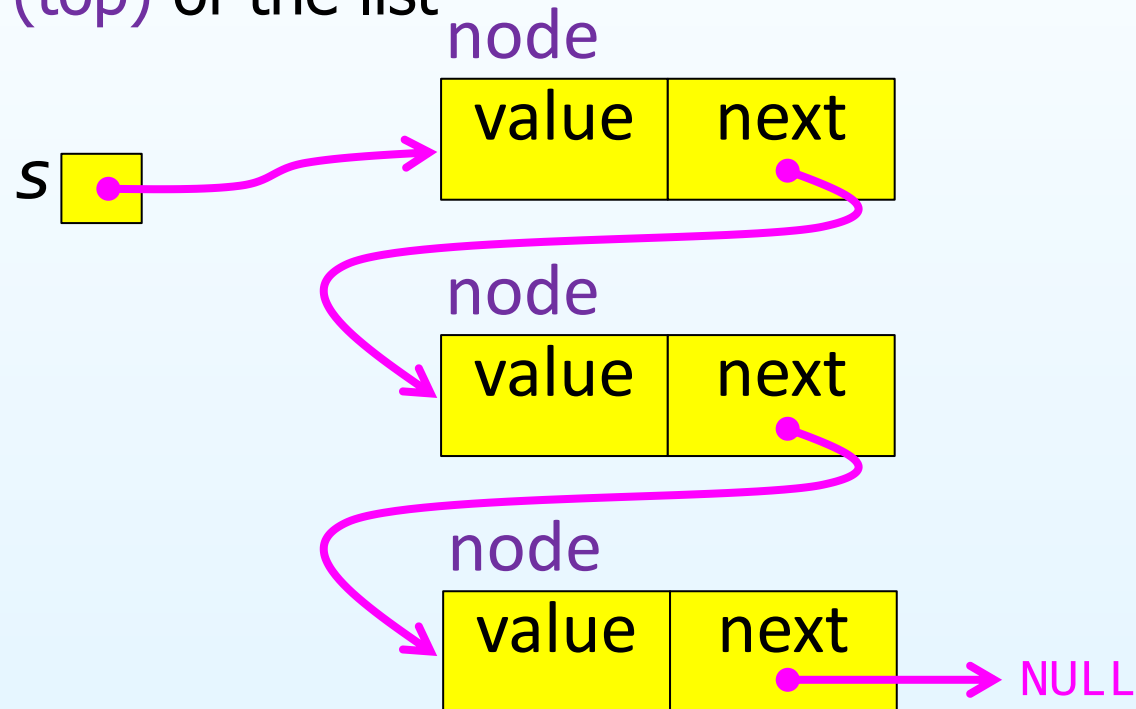

---

- If the stack is **full**, **reallocate** a huge new array and **move** everything over

# Stack: Pointer Implementation

Basic idea:

- Allocate **nodes** for elements, and link them as a list
- Form a stack by manipulating push and pop operations at the **head (top)** of the list

# List-based Stack: Construction

Assume that all data are positive integer

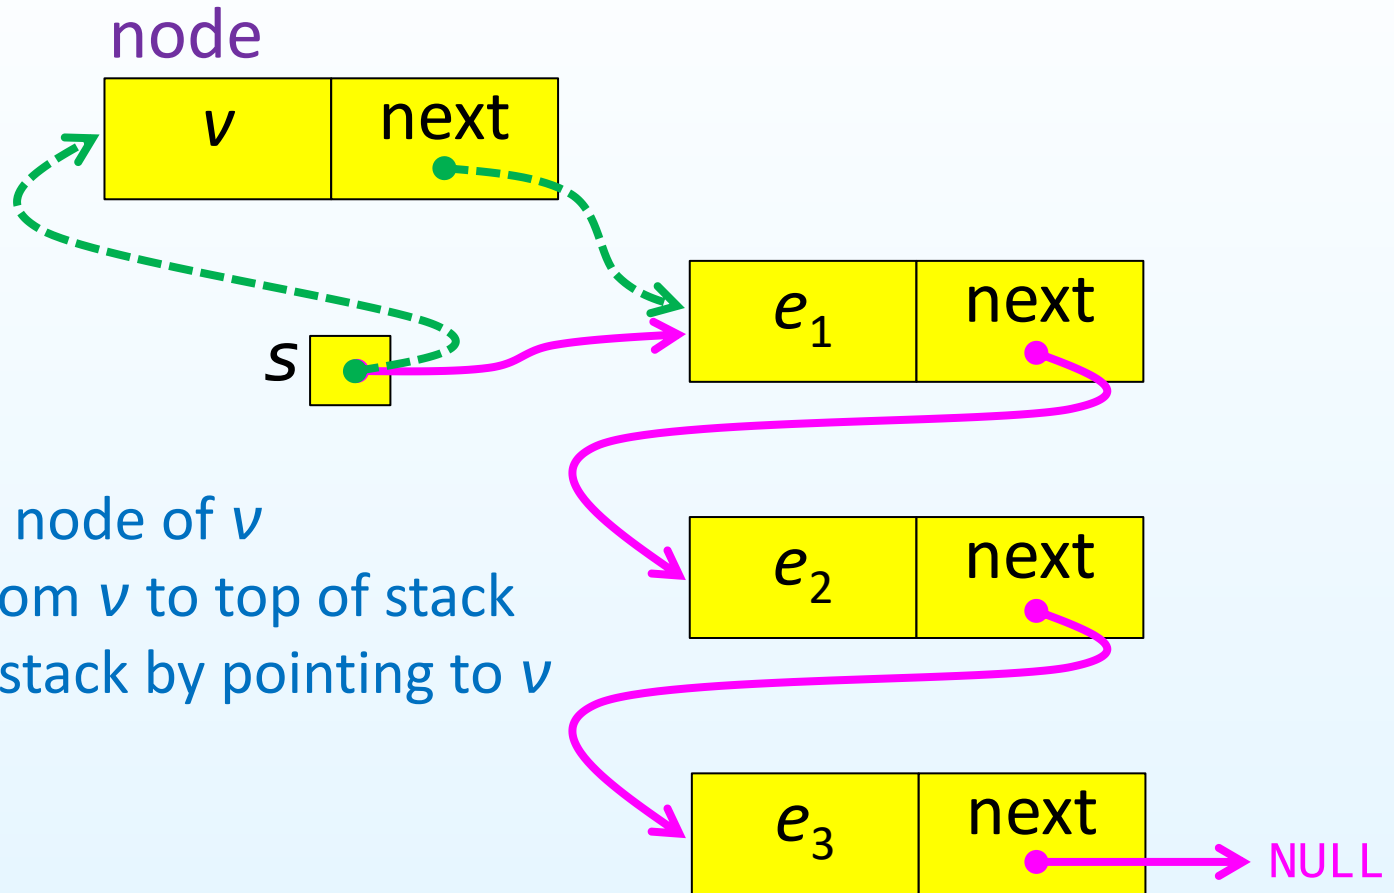

```
1: #include <stdio.h>
2: #include <stdlib.h>
3:
4: typedef struct node {
5:     int value;
6:     struct node *next;
7: } node_t;
8:
9: typedef node_t stack_t;
10:
11: int main(void) {
12:     stack_t *s = NULL;
13:     return 0;
14: }
```

node

# List-based Stack: push() Operation

Push a value  $v$  at the top of stack  $s$

1. Allocate a new node of  $v$
2. Create a link from  $v$  to top of stack
3. Change top of stack by pointing to  $v$

# List-based Stack: push() Operation

Push a value  $v$  at the top of stack  $s$

```
1: void push(stack_t *s, int v) {  
2:   node_t *node = (node_t *)malloc(sizeof (node_t));  
3:   node->value = v;  
4:   node->next = NULL;  
5:  
6:   node->next = s;  
7:   s = node;  
8: }
```

```
int main(void) {  
  stack_t *s = NULL;  
  push(s, 10);  
  return 0;  
}
```

# List-based Stack: push() Operation

Push a value  $v$  at the top of stack  $s$

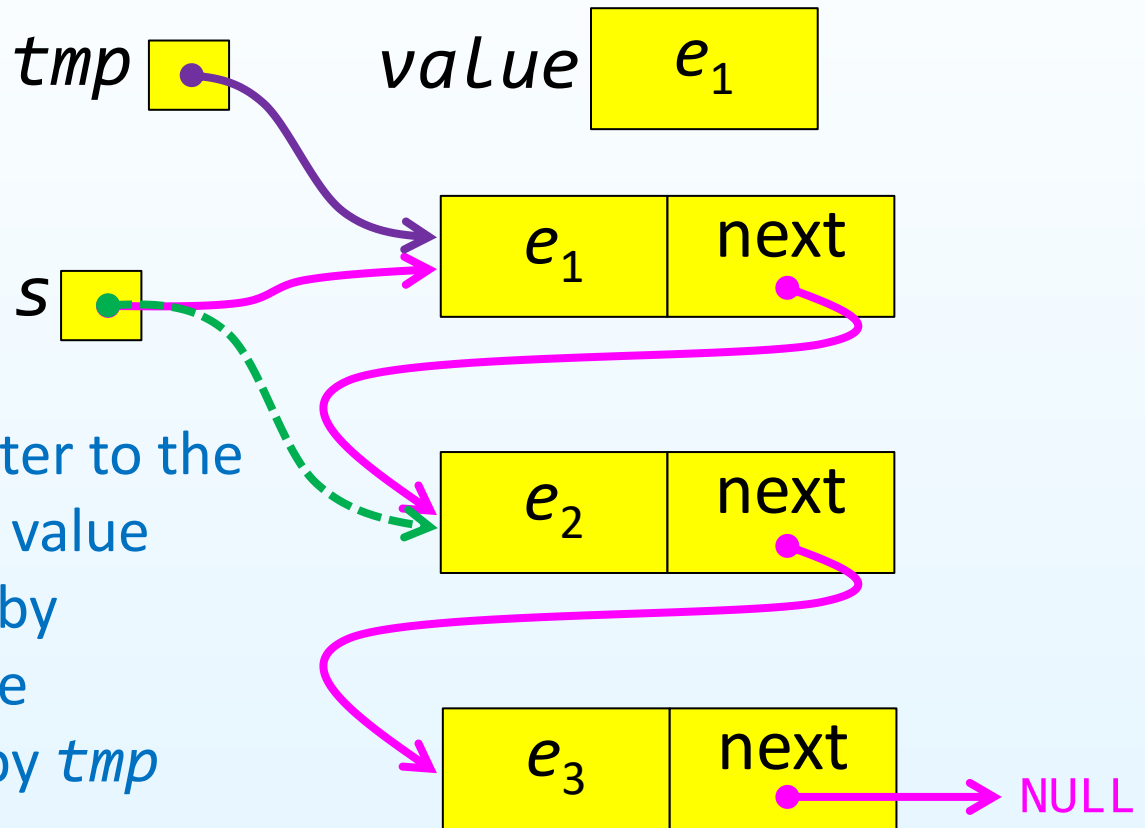

```
1: void push(stack_t **s, int v) {  
2:   node_t *node = (node_t *)malloc(sizeof (node_t));  
3:   node->value = v;  
4:   node->next = NULL;  
5:  
6:   node->next = *s;  
7:   *s = node;  
8: }
```

```
int main(void) {  
  stack_t *s = NULL;  
  push(&s, 10);  
  push(&s, 15);  
  return 0;  
}
```

# List-based Stack: pop() Operation

Remove the top of stack  $s$  and then return that value

1. Assign a temporary pointer to the top of stack, and get the value
2. Change the top of stack by pointing to the next node
3. Free the node pointing by  $tmp$

# Exercise 2: Other Operations

---

Implement the following functions for a **list-based stack**

- `pop()` – remove the top element of stack  $s$ 
  - Return  $v$  if the stack is not empty, otherwise -1
- `top()` – peek the top element of stack  $s$ 
  - Return  $v$  if the stack is not empty, otherwise -1
- `is_empty()` – check whether stack  $s$  is empty
  - return 1 if the stack is empty, otherwise 0

# List-based Stack: Running Time

---

Operation	Running Time
push()	$O(1)$
pop()	$O(1)$
top()	$O(1)$
is_empty()	$O(1)$
make_empty()	$O(n)$

# Limitation of List-based Stack

---

- Potentially **a lot of calls** to `malloc()` and `free()` if the stack is actively used
  - In practice, memory allocation and release require **expensive** trips through the operating system

How can you solve this problem?

# Application: Balancing Symbols

Are the followings correct?

- Arithmetic expression

$$(1+5*(17-2)/(6*3))$$

- Python syntax

```
print(''He said, "I 'do not' care."')
```

- HTML code

```
<html>  
<head><title>hello</title></head>  
<body>test</body>  
</html>
```

# Application: Balancing Symbols

$(1+5*(17-2)/(6*3))$

1. Create an empty stack
2. If encounter ' ( ', push onto stack
3. If encounter ' ) ',
  - 3.1 If stack is empty, report error
  - 3.2 Else, pop the stack
  - 3.3 If the popped value is not ' ( ', report error
4. If EOF and stack is not empty, report error

# Application: Balancing Symbols

1

↓  
(1+5\*(17-2)/(6\*3))  
push(' ( ' );

2

↓  
(1+5\*(17-2)/(6\*3))  
push(' ( ' );

3

↓  
(1+5\*(17-2)/(6\*3))  
sym = pop();  
→ Match

4

↓  
(1+5\*(17-2)/(6\*3))  
push(' ( ' );

5

↓  
(1+5\*(17-2)/(6\*3))  
sym = pop();  
→ Match

6

↓  
(1+5\*(17-2)/(6\*3))  
sym = pop();  
→ Match

# Application: Arithmetic Expression

What is the result of following expressions?

- Infix notation

$$10 + 6 * 5 / 2 - 4$$

- Postfix notation

$$10 \ 6 \ 5 \ * \ 2 \ / \ + \ 4 \ -$$

- Prefix notation

$$+ \ 10 \ - \ * \ 6 \ / \ 5 \ 2 \ 4$$

# Application: Infix to Postfix Conversion

10 + 6 \* 5 / 2 - 4

## Algorithm

```
1: s ← create_stack()
2: while (data ← input() and data != EOF)
3:     if (data is an operand)
4:         print(data)
5:     if (data is an operator)
6:         while (!is_empty(s))
7:             op ← top(s)
8:             if (op has higher precedence than or equal to data)
9:                 op ← pop(s)
10:                print(op)
11:            else
12:                break
13:        push(s, data)
14:
15: while (!is_empty(s))
16:     op ← pop(s)
17:     print(op)
```

# Application: Infix to Postfix Conversion

10 + 6 \* 5 / 2 - 4

Input	Stack	Output
10 + 6 * 5 / 2 - 4		10
10 + 6 * 5 / 2 - 4	+	10
10 + 6 * 5 / 2 - 4	+	10 6
10 + 6 * 5 / 2 - 4	+	10 6
10 + 6 * 5 / 2 - 4	+	10 6 5
10 + 6 * 5 / 2 - 4	+	10 6 5 *
10 + 6 * 5 / 2 - 4	+	10 6 5 * 2
10 + 6 * 5 / 2 - 4	+	10 6 5 * 2 /
10 + 6 * 5 / 2 - 4	+	10 6 5 * 2 / +
10 + 6 * 5 / 2 - 4	+	10 6 5 * 2 / + 4
10 + 6 * 5 / 2 - 4	-	10 6 5 * 2 / + 4 -

# Other Applications of Stack

---

- Backtracking
  - A recursive algorithm which is used for solving the optimization problem
- Function calls
  - Whenever you invoke a function, the address of the calling function gets stored in the stack. This helps in going back when the called function is terminated
- Memory management
  - The stack segment of memory
- Depth-first search

# Queue ADT

# What is a Queue ADT?

- Data:
  - Elements stored in a list linearly, but are allowed insertion at **one end** and deletion at **the other end**
  - This mechanism is called **FIFO** – First in, First out
- Common operations:
  - `enqueue(queue, value)`
  - `dequeue(queue)`
  - `is_empty(queue)`
  - `is_full(queue)`
  - ...

# Queue Implementations

---

- Two types of implementation
  - Array-based queue
  - Pointer-based queue

# Queue: Array Implementation

Basic idea:

- **Allocate** a big array (of size capacity)
- **Keep track** two ends (using variables front and rear)

How should we initialize both variables?

# Queue: Array-based Construction

Assume that all data are positive integer

```
1: #include <stdio.h>
2: #include <stdlib.h>
3:
4: typedef struct queue {
5:     int *arr;        // array-based queue
6:     int capacity;    // size of queue
7:     int front;       // position of front
8:     int rear;        // position of rear
9: } queue_t;
10:
11: queue_t create(int size) {
12:     queue_t q = {NULL, size, 0, -1};
13:     q.arr = (int *)malloc(sizeof (int) * size);
14:     return q;
15: }
16: int main(void) {
17:     queue_t q = create(100);
18:     return 0;
19: }
```

# Array-based Queue: enqueue() Operation

Insert a value  $v$  into queue  $q$

```
1: int enqueue(queue_t *q, int v) {
2:     if (q->rear == q->capacity-1)    // queue is full
3:         return 0;
4:
5:     q->rear++;                        // enqueue normally
6:     q->arr[q->rear] = v;
7:     return 1;
8: }
```

# Array-based Queue: dequeue() Operation

Remove a value from queue  $q$  and return it

```
1: int dequeue(queue_t *q) {
2:     int v;
3:
4:     if (q->front > q->rear)           // queue is empty
5:         return 0;
6:
7:     v = q->arr[q->front];              // dequeue normally
8:     q->front++;
9:     return v;
10: }
```

# Array-based Queue: Running Time

Operation	Running Time
create()	$O(1)$
enqueue()	$O(1)$
dequeue()	$O(1)$
is_empty()	$O(1)$
make_empty()	$O(1)$
is_full()	$O(1)$
destroy()	$O(1)$

# Limitation of Array-based queue

- If the queue is **full**, **reallocate** a huge new array and **move** everything over
- A simple implementation of `dequeue()` can lead to a lot of unused spaces

How can you solve this problem?

# Queue: Pointer Implementation

Basic idea:

- Allocate **nodes** for elements, and link them as a list
- Form a queue with front and rear pointers

# List-based Stack: Construction

Assume that all data are positive integer

```
1: #include <stdio.h>
2: #include <stdlib.h>
3:
4: typedef struct node {
5:     int value;
6:     struct node *next;
7: } node_t;
8:
9: typedef struct queue {
10:     node_t *front;
11:     node_t *rear;
12: } queue_t;
13:
14: int main(void) {
15:     queue_t q = {NULL, NULL};
16:     return 0;
17: }
```

node

queue

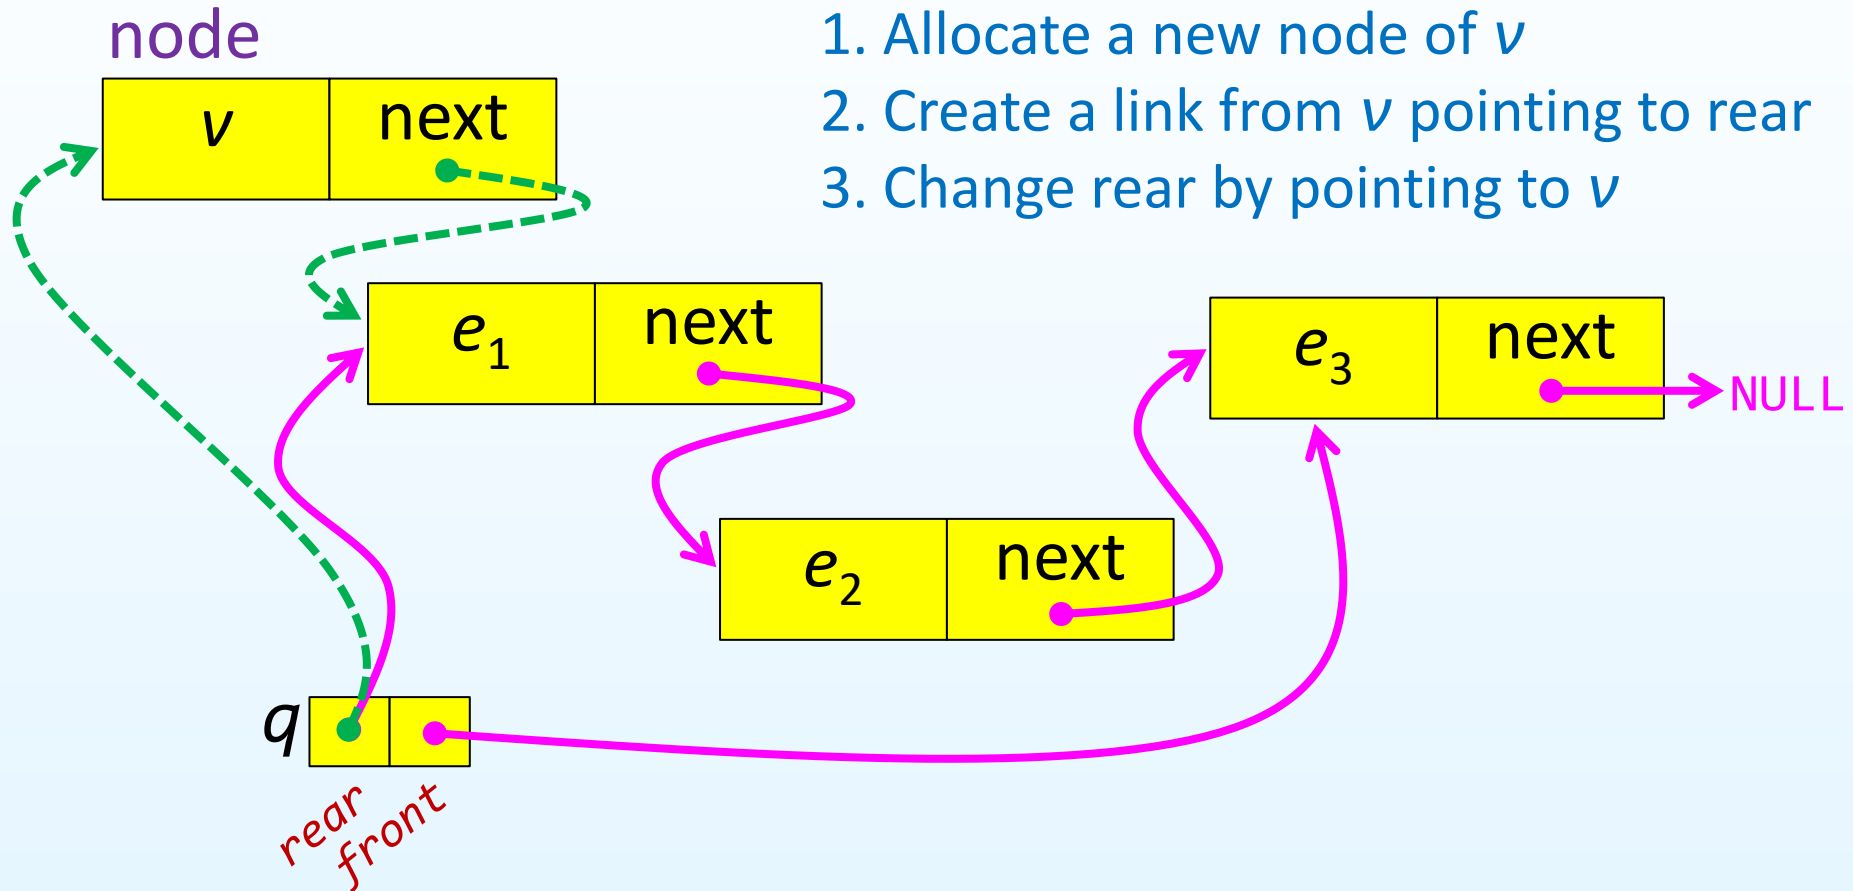

# List-based Queue: enqueue() Operation

Insert a value  $v$  into queue  $q$

1. Allocate a new node of  $v$
2. Create a link from  $v$  pointing to rear
3. Change rear by pointing to  $v$

# List-based Queue: enqueue() Operation

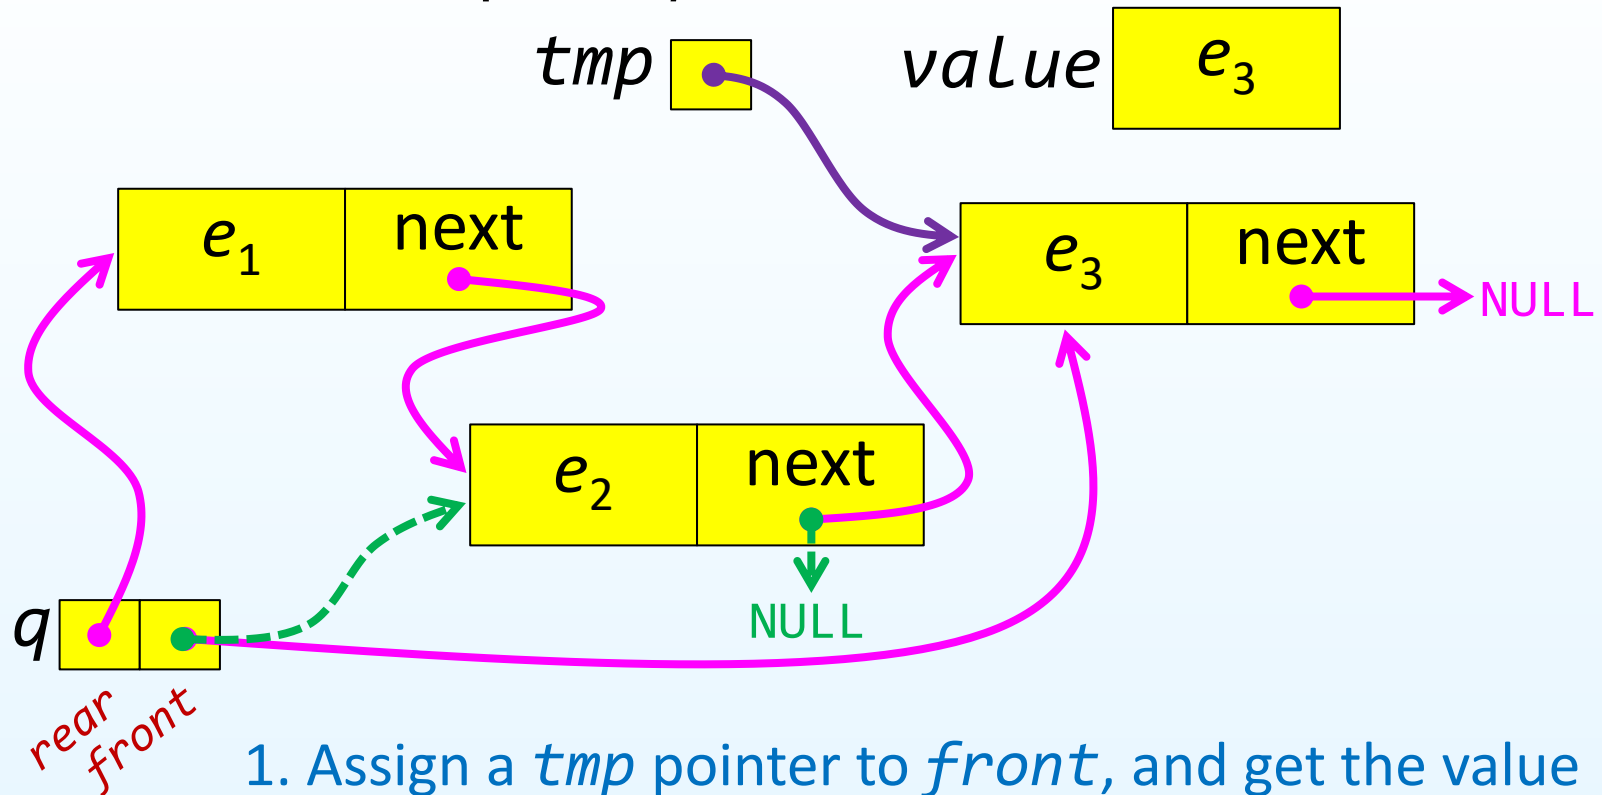

Insert a value  $v$  into queue  $q$

```
1: void enqueue(queue_t *q, int v) {
2:     node_t *node = (node_t *)malloc(sizeof (node_t));
3:     node->value = v;
4:     node->next = NULL;
5:
6:     node->next = q->rear;
7:     q->rear = node;
8:
9:     if (q->front == NULL)
10:         q->front = node;
11: }
```

1. Allocate a new node of  $v$
2. Create a link from  $v$  pointing to rear
3. Change rear by pointing to  $v$

# List-based Queue: dequeue() Operation

Remove a value from queue  $q$  and return it

1. Assign a  $tmp$  pointer to  $front$ , and get the value
2. Change  $front$  pointing to the 2<sup>nd</sup> last node of list
3. Change next of 2<sup>nd</sup> last node pointing to NULL
4. Free the node pointing by  $tmp$

# List-based Queue: dequeue() Operation

Remove a value from queue  $q$  and return it

```
1: int dequeue(queue_t *q) {
2:     node_t *tmp = NULL;
3:     int value = 0;
4:
5:     if (q->front == NULL)           // queue is empty
6:         return -1;
7:
8:     tmp = q->front;
9:     value = q->front->value;
10:
11:    if (q->front == q->rear) {        // queue has only one node
12:        q->front = NULL;
13:        q->rear = NULL;
14:    } else {
15:        q->front = q->rear;           // find 2nd last node
16:        while (q->front->next != tmp)
17:            q->front = q->front->next;
18:        q->front->next = NULL;        // set 2nd last node pointing to NULL
19:    }
20:    free(tmp);
21:    return value;
22: }
```

# List-based Queue: Running Time

Operation	Running Time
enqueue()	$O(1)$
dequeue()	$O(n)$
is_empty()	$O(1)$
make_empty()	$O(n)$

How can you reduce the cost?

Front should point to head and rear should point to tail.

# Limitation of List-based Queue

---

- Potentially **a lot of calls** to `malloc()` and `free()` if the queue is actively used
  - In practice, memory allocation and release require **expensive** trips through the operating system

How can you solve this problem?

# Applications of Queue

---

- Printer queue
- Web server queue
- Call Center phone system
- Breadth-first search

# Any Question?

# Solution to Exercise 1

Remove the top element of stack  $s$

```
1: int pop(stack_t *s) {  
2:     int v;  
3:     if (s->topstack == -1)           // stack is empty  
4:         return -1;  
5:  
6:     v = s->arr[s->topstack];  
7:     s->topstack--;  
8:     return v;  
9: }
```

Peek the top element of stack  $s$

```
1: int top(stack_t s) {  
2:     if (s.topstack == -1)           // stack is empty  
3:         return -1;  
4:  
5:     return s.arr[s.topstack];  
6: }
```

# Solution to Exercise 1

---

Check whether stack  $s$  is empty

```
1: int is_empty(stack_t s) {  
2:     return (s.topstack == -1)? 1 : 0;  
3: }
```

Check whether stack  $s$  is full

```
1: int is_full(stack_t s) {  
2:     return (s.topstack == s.capacity-1)? 1 : 0;  
3: }
```

# Solution to Exercise 2

Remove the top element of stack  $s$

```
1: int pop(stack_t **s) {
2:     node_t *tmp = NULL;
3:     int     v;
4:
5:     if ((tmp = *s) == NULL)        // stack is empty
6:         return -1;
7:
8:     v = tmp->value;
9:     *s = tmp->next;
10:    free(tmp);
11:    return v;
12: }
```

# Solution to Exercise 2

---

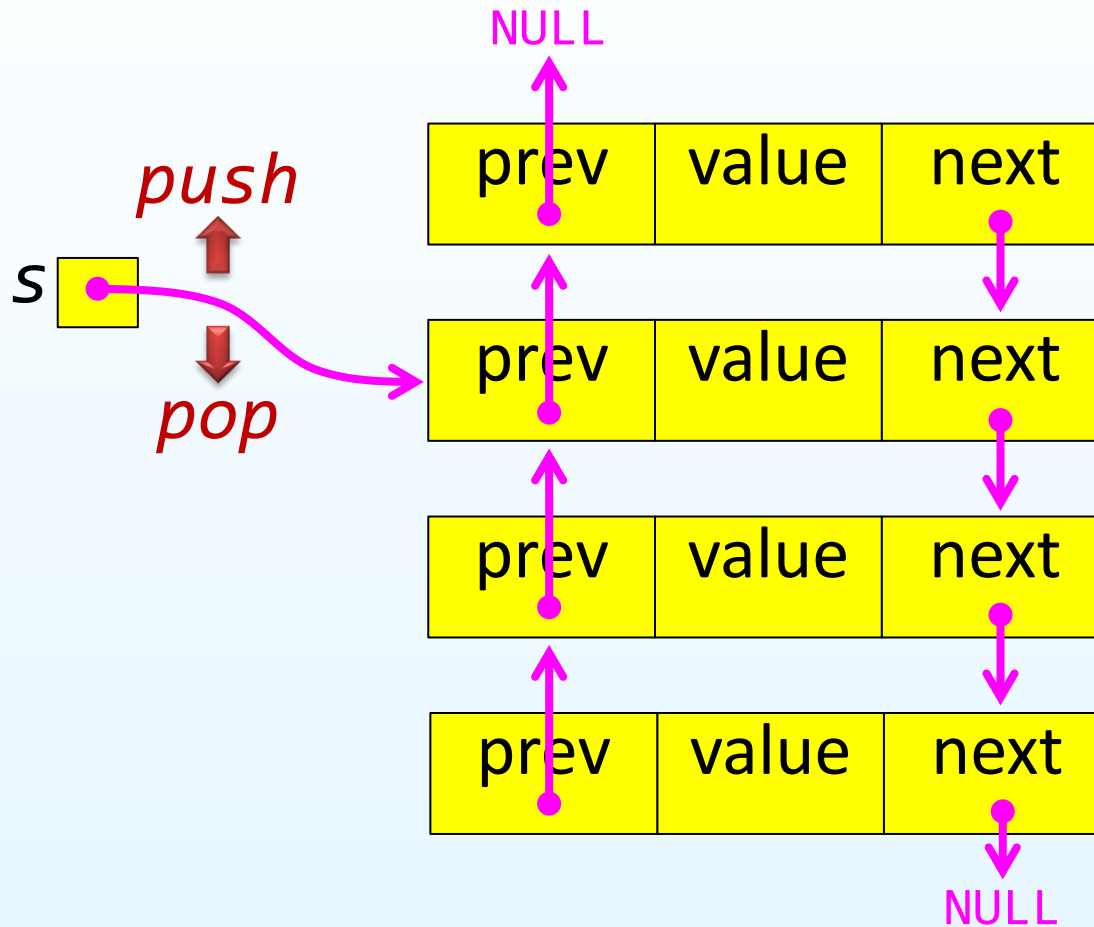

Peek the top element of stack  $s$

```
1: int top(stack_t *s) {  
2:     if (s == NULL)           // stack is empty  
3:         return -1;  
4:  
5:     return s->value;  
6: }
```

Check whether stack  $s$  is empty

```
1: int is_empty(stack_t *s) {  
2:     return (s == NULL)? 1 : 0;  
3: }
```

# Extended List-based Stack

# Circular Array-based Queue
